ABSTRACT

A study on the variation of leaf venation pattern was undertaken on 43 taxa belonging to 19 genera of Sapindaceae in Malaysia. Results showed that there were 17 venation patterns observed based on the leaf lamina venation, ultimate marginal and veinlet patterns. A total of 15 taxa showed bi-veinlets, 15 taxa uni-veinlets, eight taxa simple veinlets, three taxa tri-veinlet patterns and two other taxa with no ending veinlets. The presence of idioblast cells on the leaf lamina surfaces, presence and localization of simple trichomes on the leaf veins or on the leaf epidermis are the diagnostic characteristics that can be used in identification of *Guioa*, *Harpullia* and *Glennebia*. Druses observed on the leaves lamina can be very useful for species identification of *Filicium decipiens* (Wight & Arn.) Thwaites. Combination of variation in the leaf venation and diagnostic characteristics found in this study have taxonomic value especially in species and genus identification and differentiation in Sapindaceae in Malaysia.

Key words: Sapindaceae, Leaf venation, Leaf anatomy, Diagnostic characters

INTRODUCTION

Sapindaceae is one of the main angiosperm plant families and includes 150 genera with ca. 2000 taxa which is widespread in tropical and subtropical regions of the world. It is well represented in South America (Adema *et al.*, 1994; van Welzen, 1999) and in Malaysia, a total of 23 genera with 62 taxa can be found in Sabah and Sarawak, and 50 taxa in 18 genera in Peninsular Malaysia (Adema *et al.*, 1994; Yap, 1989). The members of Sapindaceae can be trees and shrubs, including lianas (*Cardiospermum*). Those taxa can be found thriving in primary and secondary rainforests, especially on forest edges, coastal vegetation and roadsides, mainly in lowlands but also on the mountains up to 3000 m (Leenhouts & Muller, 1976).

The family is also important for the regional economy, as a source of edible fruits and seeds

including *Dimocarpus longan* var. *longan* Leen., *Litchi chinensi* Sonn., *Nephelium lappaceum* L. and *N. ramboutan-ake* (Labill.) Leen. (Adema *et al.*, 1994). Other than that, wood of some taxa of Sapindaceae is useful as timber (Seibert, 1998) and also for medicinal purposes, vegetables, soap or fish poisons (van Welzen, 1992). The family is characterized by alternate and spiral leaves arrangement, mostly paripinnate, sometimes imparipinnate, trifoliate or simple in a few genera; inflorescence axillary to terminal, spike-like to heavy branching; flowers male or bisexual, the latter usually with stamens reduced with filmy appendage; fruits developing from all or one or two of the ovary lobes and seeds covered with sarcotesta, mesocarp or aril. Most genera and species when in sterile conditions are difficult to identify when collected without inflorescence and fruits (Leenhouts & Muller, 1976).

Based on previous studies, leaves are definitely the main characteristic used for identification

* To whom correspondence should be addressed.

including other morphology, anatomy, phytochemistry and others (Inamdar *et al.*, 1983). In other families' leaf anatomy, have been used for taxa identification, for examples *Euphorbia* (Euphorbiaceae) (Sehgal & Paliwal, 2008), *Bouea*, *Mangifera* and *Spondias* in Anacardiaceae (Mohd Norfaizal & Latiff, 2014), *Macaranga* in Euphorbiaceae (Mohd Norfaizal *et al.*, 2012), *Cardiospermum* in Sapindaceae (Solis & Ferrucci, 2006) and some genera in Dipterocarpaceae (Noraini & Cutler, 2009). All these studies have proved the significance of leaf anatomy in identification of various genera and species, whenever complete specimens are not available. Therefore this study aims to investigate microscopic characteristics of venation patterns and variations of the selected taxa Sapindaceae, as to find out whether these characteristics could be used as a diagnostic characteristic and taxonomic values for the taxa identification.

MATERIALS AND METHODS

Fresh and herbarium samples of a total of 43 taxa of Sapindaceae were used in this study. Details of the taxa and collections are given in Table 1. The fresh specimens used in this study were obtained from many localities in Malaysia, including Sabah, Sarawak, in Peninsular Malaysia includes Taman Negara, Royal Belum State Park and also in Malaysian Agricultural Research and Development Institute (MARDI) Serdang Rare fruit Gene bank. Dried specimens were obtained and analysed from the MARDI Herbarium (MDI), Forest Research Institute Malaysia (KEP) and Universiti Kebangsaan Malaysia, Bangi (UKMB) Herbaria.

The fresh leaf specimens collected were fixed in AA (70% ethanol, 30% acetic acid ratio of 1:3); the dried herbarium samples were boiled depending on the taxa, as thick specimens may take up to 15 minutes of boiling to soften the leaves structure. Approximately 1 x 1 cm sample of the leaf lamina and margin area were cleared using Basic Fuchsin solution (10% Basic Fuchsin and 10% KOH, Sigma Aldrich) in an oven at 60°C for 1 to 2 days, depending on the thickness of the leaf specimen. The cleared leaf specimens were then dehydrated in an alcohol series, cleared in xylene and mounted on slides using Canada Balsam (Sigma Aldrich Chemical, England). The samples were then placed in an oven at 60°C for 2 weeks. The slides were photographed using a digital camera (Olympus BX43F, Tokyo) mounted on an Olympus microscope (Olympus Soft Imaging Solutions GmbH, Münster, Germany). The leaf venation patterns were observed using Cellsens Software (Cellsens, Tokyo Japan)

under 10x, 20x, and 40x magnification. Details of the analysis and descriptions of the leaf venation types followed the classification of Hickey (1979).

RESULTS AND DISCUSSION

The variation of leaf venation patterns of angiosperms was extensively studied and classified by Hickey (1979) and Sun *et al.* (1997), to name the most comprehensive treatments. Leaf architecture is primarily used for classification such as the leaf shape, leaf margin structure and as many as possible characters. Indeed, the first observation and characterization of an angiosperm leaf venation pattern starts by observing the primary veins and then proceeded to the secondary veins that branch off from the primary veins. According to Dickinson (2000), leaf veins are primarily cylindrical bundles of vascular tissue that occur mainly in the mesophyll of leaf lamina and in dicotyledons, it consists of one to more branched major veins and minor veins that usually end with free ending veinlets within the areoles. Veinlet can be branched or unbranched and end in one to three tracheid's.

Leaf venation pattern for a few sub-temperate species of Sapindaceae was studied by Metcalfe and Chalk (1950). It forms the elements that express the leaf structure such as the lamina venation pattern, marginal configuration and gland existence, also serves ultimately for the taxonomists to document the function of leaf venation structure in taxa identification. This is supported by leaf venation patterns have high taxonomic value and suggested that each taxon has a constant number of veins that can be used for identification and for genus confirmation (Sehgal & Phaliwal, 2008).

In Sapindaceae, leaf characters play an important role in supporting identification and classification, such as the size and shape of petiole and leaf blade, the number of nerves and secretory cells and trichomes that are usually diagnostic especially when complete specimens are available for observation (Radlkofler, 2009). Combination of marginal venation and areolar venation patterns for every taxon are unique, even those taxa that are classified under one genus, for example *Nephelium*. Among the 17 taxa of *Nephelium* studied, the veinlet endings vary greatly among them, namely uni-, simple and linear, bi- or tri-veinlets, with their ultimate marginal venation as complete or incomplete (Table 2). The abundance of idioblast cells on the lamina surface of *Guioa* and *Glenneia* can be a diagnostic character for them (Figure 4D). Druses were also observed in *Filicium decipiens* (Wight & Arn.) Thwaites, a single introduced species of Sapindaceae in Malaysia (Figure 4A). The

<i>Pometia pinnata</i> f. <i>pinnata</i>	+					+
<i>Trigonacharas acuta</i>	+					+
<i>Xerospermum noronhianum</i>		+		+		

presence of swollen veinlets or swollen tracheid's, cystolith cells and trichomes can also be used as additional characters for the differentiation of taxa among groups. For example, swollen veinlets are present in *Allophylus cobbe* (L.) Raeusch (Figure 4B) and trichomes on the leaf venation can be observed in *Cardiospermum halicacabum* L. (Figure 4C).

A total of 43 taxa belonging to 19 genera were extensively studied for their leaf venation patterns and the results are summarised in Table 4. Five veinlet patterns were observed from this study,

namely no ending veinlets, simple and linear veinlets, uni-veinlets, bi-veinlets and tri-veinlets. In particular, two species include *Litchi chinensis* Sonn. and *Dimocarpus fumatus* Leenh. showed no ending veinlets and this is diagnostic for them. While others showed either uni-, or simple and linear, or bi- or tri-veinlets and these can be the diagnostic characters for taxa identification.

Two types of ultimate marginal venation were observed in this study. Type 1 is an incomplete ultimate marginal venation, consisting of freely ending veinlets directly adjacent to the margin and

this is showed by 34 taxa (Figure 1A-H). Type 2 is a complete or closed ultimate marginal venation, which refers to higher vein order fused into a vein running just inside the margin and showed by only nine taxa (Figure 2A-H). From the areolar venation observed, it also showed clearly two types of areolar venation, namely Type 1, for which the majority of the leaf venation which consists of incomplete ending veinlets (Figures 3A, B, C & E) and Type 2,

a closed venation (Figure 3D), that is observed only in *Litchi chinensis* Sonn. and *Dimocarpus fumatus* Leen.

Cluster analysis using *Gower General Similarity Coefficient* was performed using 11 characters such as the leaf marginal venation, areolar venation and diagnostic characters (Table 3). It is clearly shown that two main clusters were obtained with similarity index 0.5. Cluster I contain 9 taxa and can be further

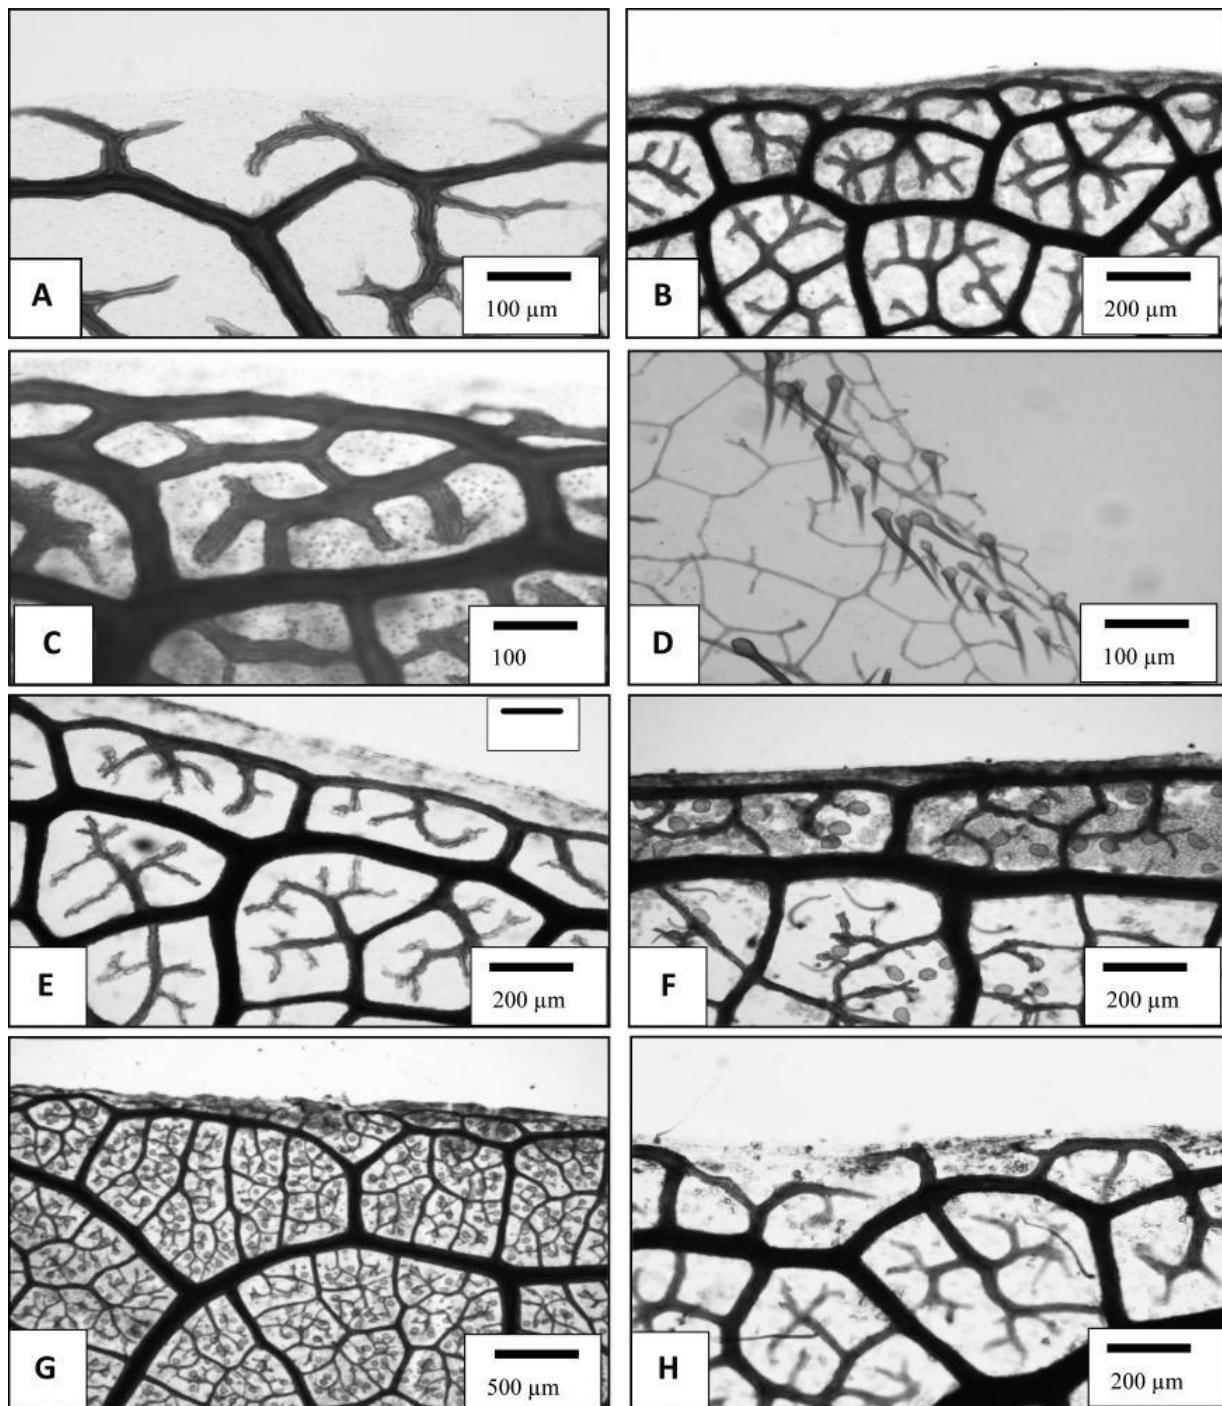

Fig. 1. Ultimate marginal venation in Sapindaceae. A. *Allophylus cobbe*, B. *Amesiodendron chinense*, C. *Arytera littoralis*, D. *Cardiospermum halicacabum*, E. *Lepisanthes amoena*, F. *Guioa bijuga*, G. *Guioa pleuropteris* and H. *Paranephelium macrophyllum*.

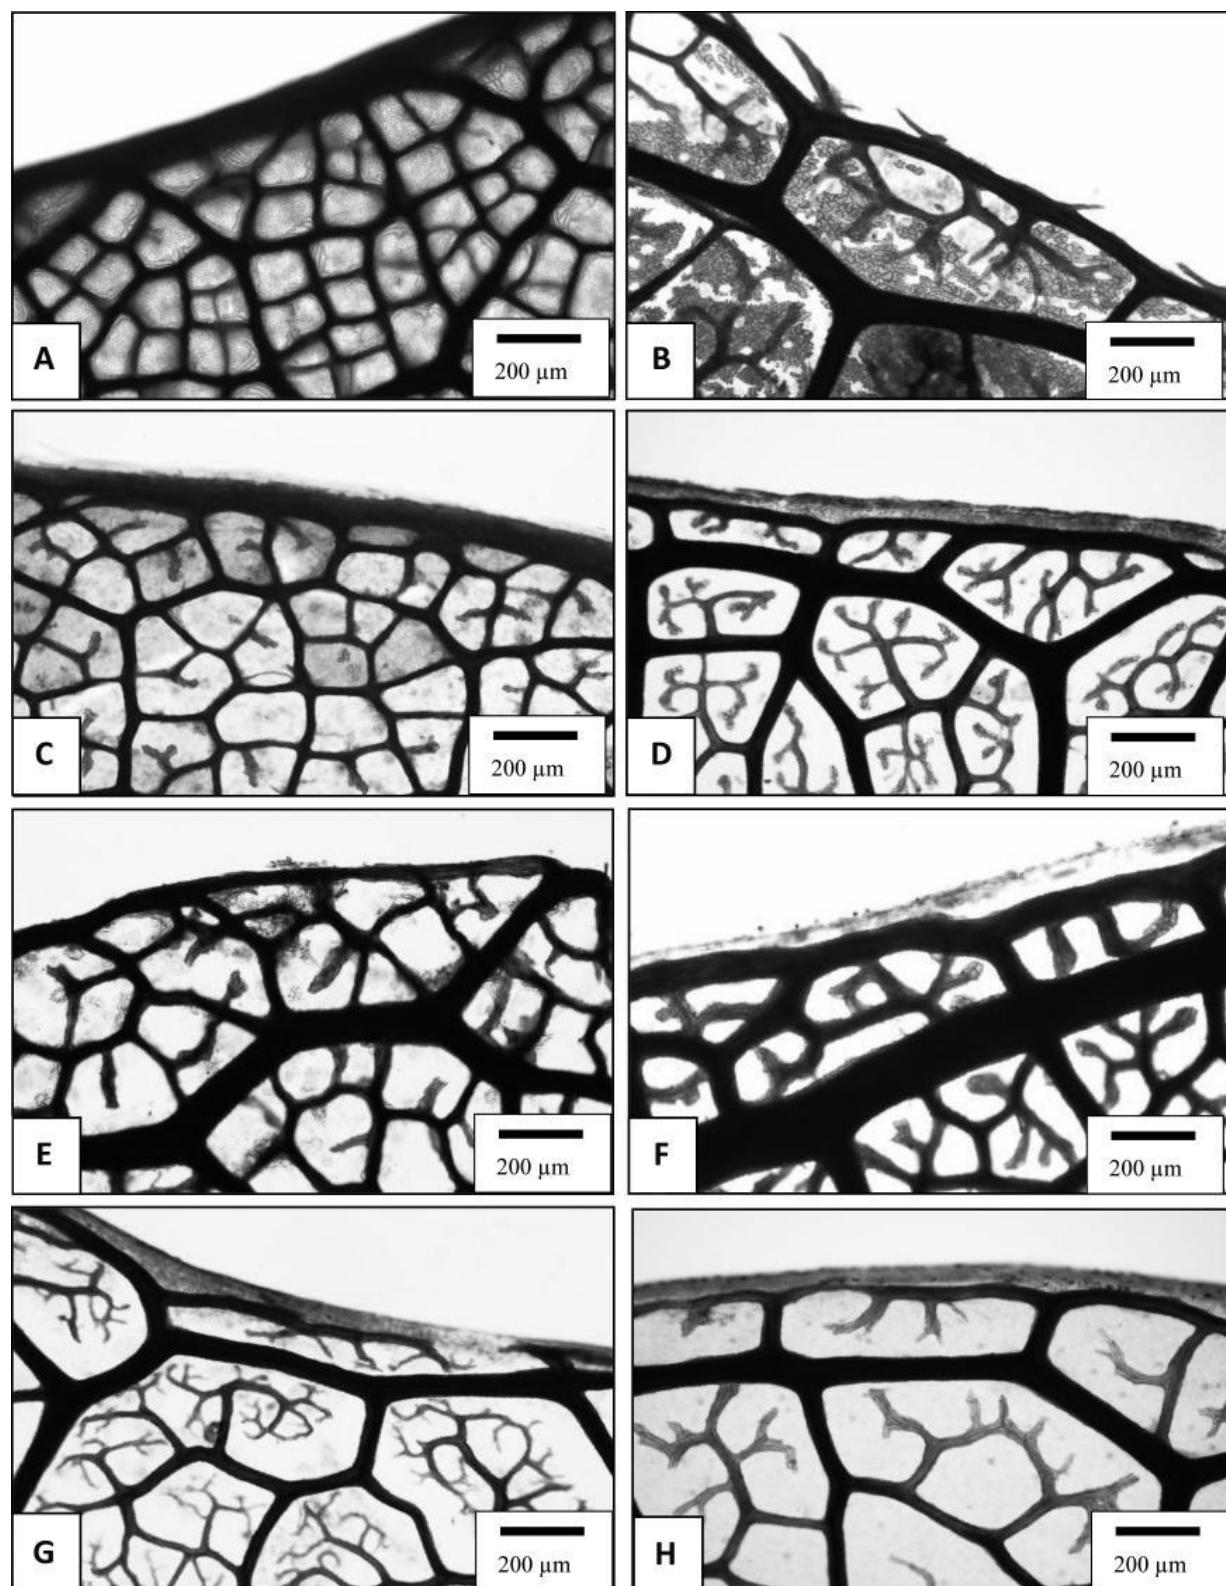

Fig. 2. Ultimate marginal venation in Sapindaceae (continued) A. *Litchi chinensis*, B. *Lepisanthes tetraphylla*, C. *Mischocarpus pentapetalus*, D. *Mischocarpus sundaicus*, E. *Nephelium cuspidatum* var. *multinerve*, F. *Nephelium cuspidatum* var. *eriopetalum*, G. *Pometia pinnata* and H. *Xerospermum noronhianum*.

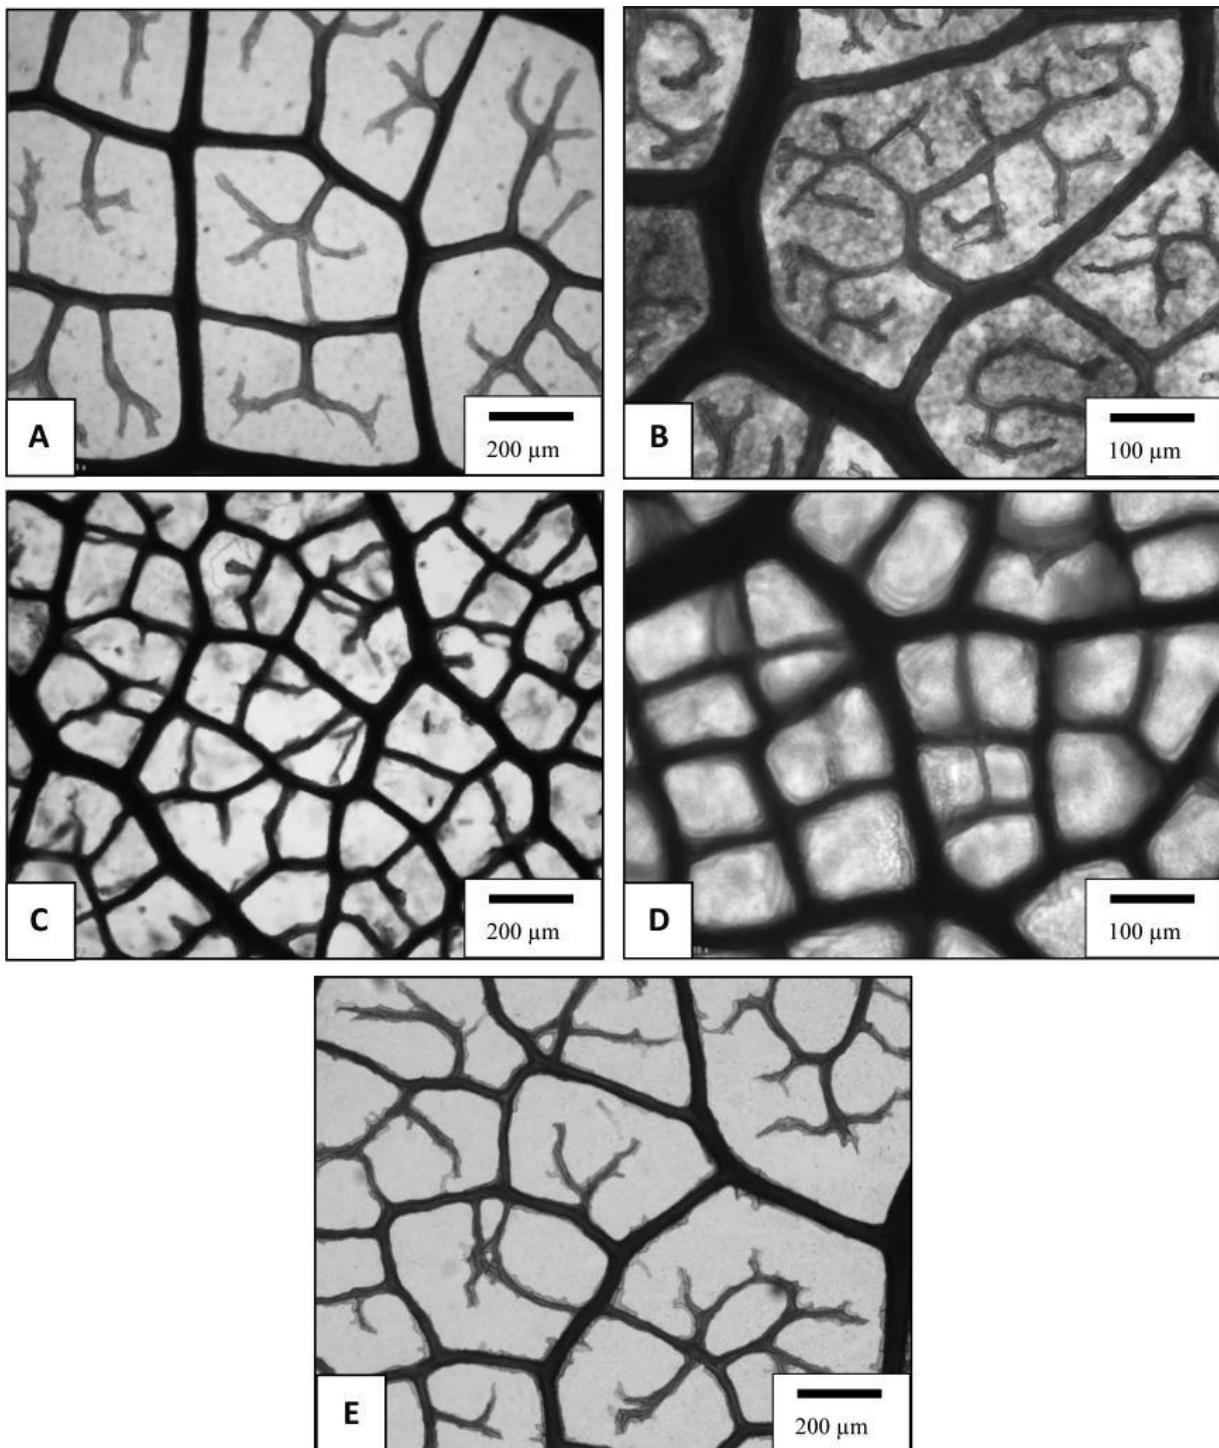

Fig. 3. Areolar venation in Sapindaceae A. Uni-veinlets, B. Tri-veinlets, C. Simple and uni-veinlets, D. No ending-veinlet and E. Bi-veinlets.

discerned into 4 sub clusters IA-ID with similarity index 0.72. Sub cluster IA consists of *Lepisanthes tetraphylla* (Vahl.) Radlk., sub cluster IB consists of *Nephelium cuspidatum* var. *multinerve* (Radlk.) Leenh., *Mischocarpus sundaicus* Blume, *M. pentapetalus* (Roxb.) Radlk. and *Dodonaea viscosa* Jacq., sub cluster IC consists of *Litchi chinensis* Sonn. and *Dimocarpus fumatus* Leenh. while sub

cluster ID contains *Dimocarpus longan* var. *longan* Leenh. and *D. longan* var. *malesianus* Leenh. All those taxa clustered in Cluster I shared the same character of closed marginal venation type.

Cluster II with similarity index 0.71 also consists of 4 subclusters too, IIA – IID. Subcluster IIA (similarity index 0.85) consists of *Para-nephelium macrophyllum* King, *Nephelium*

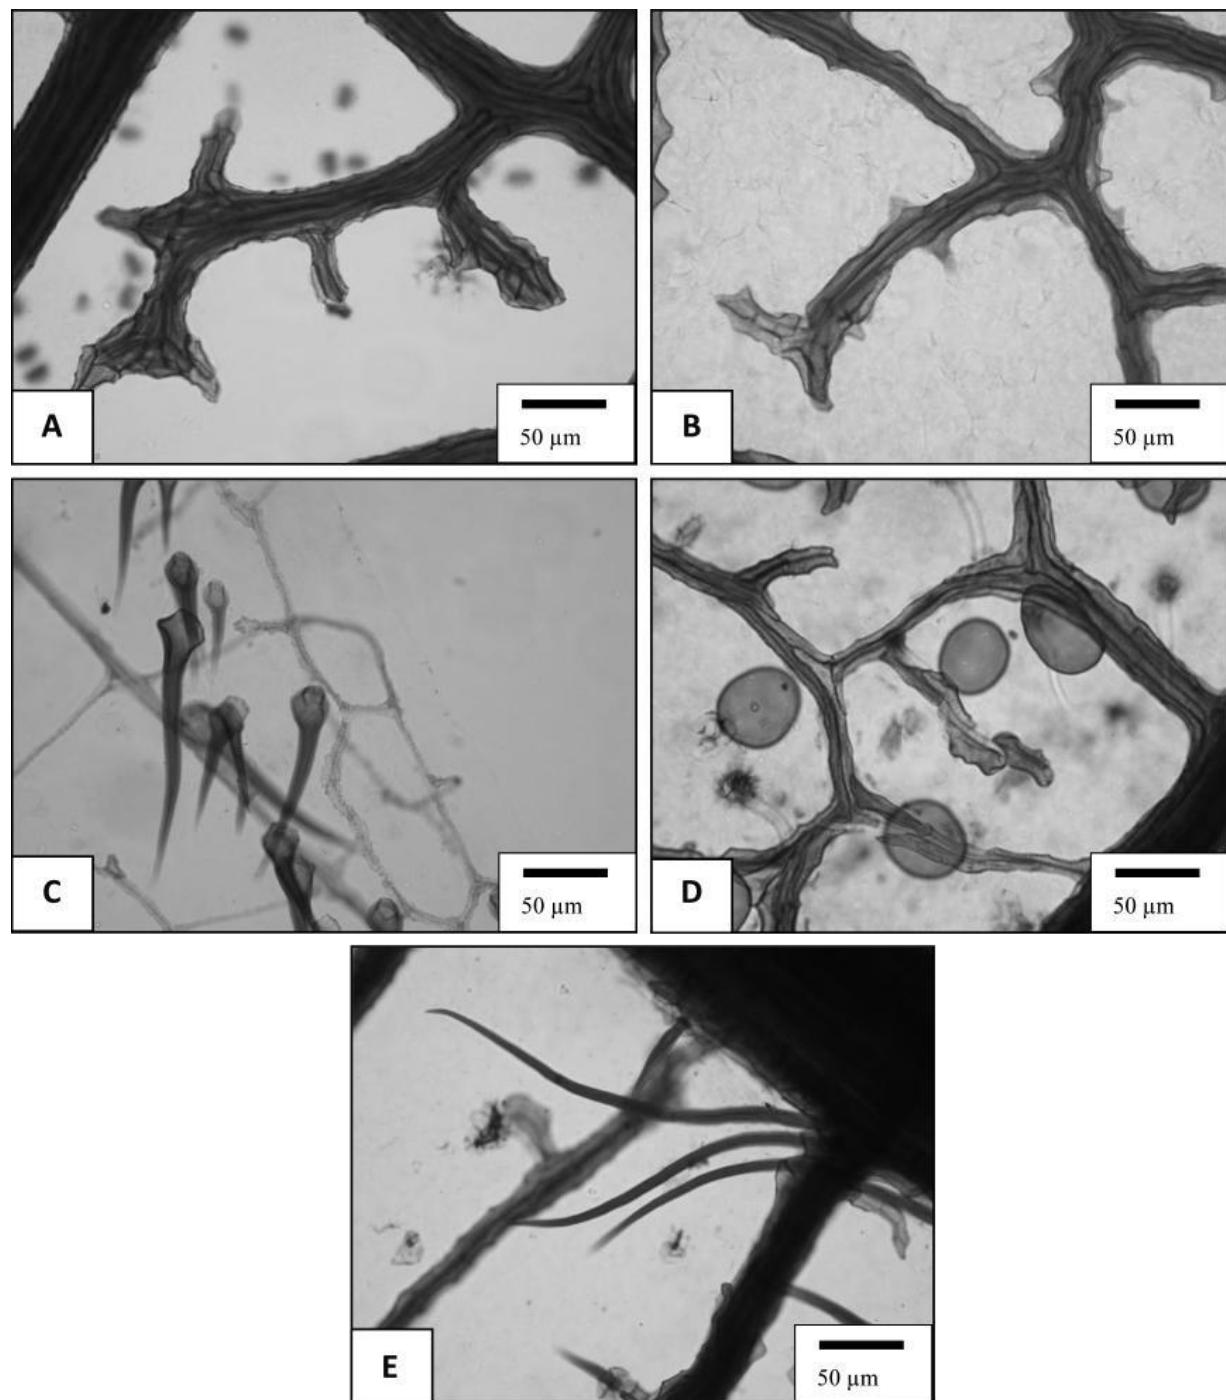

Fig. 4. Other anatomical characters in the veins of Sapindaceae. A. Druses on the leaf lamina surface observed in *Filicium decipiens*, B. Swollen tracheid's in *Allophylus cobbe*, C. Simple trichomes restricted on the leaves margin in *Cardiospermum halicacabum*, D. Idioblast cells observed in *Guioa* spp. and E. Simple trichomes observed on leaves lamina of *Glenneia penangensis*.

melliferum Gagnep., *N. cuspidatum* var. *ophoides* Blume, *Lepisanthes senegalensis* (Poir.) Leenah., *Cardiospermum helicacabum* L. and *Amesiodendron chinense* (Merr.) Hu, Subcluster IIB (similarity index 0.73) contains *Pometia pinnata* f. *pinnata* J.R. Forst. & G. Forst., *P. pinnata* f. *glabra* J.R. Forst. & G. Forst., *P. pinnata* f. *macrocarpa* J.R. Forst. & G. Forst., *N. uncinatum* Radlk. ex Leenah.,

N. melanomiscum Radlk., *N. maingayi* Hiern., *N. cuspidatum* var. *robustum* Blume, *Harpullia arborea* (Blanco.) Radlk. and *Lepisanthes fruticosa* (Roxb.) Leenah., Subcluster IIC (similarity index 0.85) consists of *Xerospermum noronhianum* (Blume) Blume, *N. juglandifolium* Blume, *N. laurinum* Blume, *Lepisanthes rubiginosa* (Roxb.) Leenah., *L. amoena* (Hassk.) Leenah., *Guioa diplopetala* (Hassk.)

Table 3. Leaf venation characteristics used in MVSP analysis

Type of characteristics	Scoring details	Analysis
Ultimate marginal venation	1. Complete or closed	Yes (1) No (0)
	2. Incomplete	Yes (1) No (0)
Areolar venation	3. Incomplete	Yes (1) No (0)
	4. Complete or Closed	Yes (1) No (0)
	5. No veinlet	Yes (1) No (0)
Type of veinlets	6. Simple veinlets (linear-curved)	Yes (1) No (0)
	7. Bi-veinlets	Yes (1) No (0)
	8. Tri-veinlets	Yes (1) No (0)
Other characters	9. Idioblasts appearance	Yes (1) No (0)
	10. Druses present	Yes (1) No (0)
	11. Trichomes present	Yes (1) No (0)

Radlk., *G. pleuropteris* (Blume) Radlk., *Filicium decipiens* (Wight & Arn.) Thwaites and *Arytera littoralis* Blume and finally subcluster IID (similarity index 0.70) consists of *Trigonachras acuta* (Hiern.) Radlk., *N. ramboutan-ake* (Labill.) Leenah., *N. hamulatum* Radlk., *N. cuspidatum* var. *eriolopetalum* Blume, *Ganophyllum falcatum* Blume and *Allophylus cobbe* (L.) Raeusch. A single species of *Guioa bijuga* (Hiern.) Radlk. was observed forming subcluster IIA.

Variation in types of veinlet combined with diagnostic characters such as idioblast and presence of druses or trichomes on the leaf surface observed in each taxon play important role in clustering all the taxa in Cluster II. There is no clear resolution in the clusters that delimit those taxa having complete or closed marginal venation or their areolar leaf venation type. Hence, it is suggested to combine these results with other anatomical and morphological evidences to get a better classification of Malaysian Sapindaceae.

However, delimitation for subfamilies was detected. Cluster I contain Sapindoideae, Nepheliaeae and Dodonaideae, while Cluster II consists members of Sapindoideae, Paullianeae,

Nepheliaeae, Doratoxyleae and Thouinaeae. It is also showed that *Litchi*, *Dimocarpus* and *Nephelium* which are the closely related were clustered in Cluster I and support the close venation morphological relationship between these genera.

CONCLUSION

The observation of variable patterns of leaf venation is taxonomically significant in the Malaysian Sapindaceae because it can be used as additional evidences, mainly in the group (subfamilies and tribes) identification of taxa and also to directly differentiate Malaysian Sapindaceae taxa such as the genera *Guioa*, *Harpullia*, *Gleneia* and species such as *Litchi chinensis*, *Xerospermum noronhianum* and *Dimocarpus fumatus* and the introduced *Filicium decipiens*. However, other taxa may require more anatomical characters such as petioles, midribs, lamina, margin, epidermal surfaces, stomata, anticlinal walls, amongst others and in combination with morphology they may be more useful in both generic and species identification and classification.

ACKNOWLEDGEMENTS

The authors wish to thank the Herbarium of MARDI, Serdang for providing some of the dried leave samples. Also, we would like to thank the curators of Herbaria KEP and UKMB for their permission to conducting analysis involving their herbarium collections. Appreciation is also extended for the financial assistance provided through MARDI's development fund – RMK11-407.
