Abstract

Tumors of the small intestine are rare. Even though the small bowel accounts for 80% of the length and 90% of the mucosal surface of the gastrointestinal tract, only 3% to 6% of gastrointestinal tumors and 1% of gastrointestinal malignancies arise from the small bowel. Leiomyoma, adenoma, lipoma, haemangioma, fibroma and hamartoma of the small intestine are considered to be benign neoplasm. Most small bowel tumors are incidental findings at operation or autopsy. Here we present a case of benign tumour of the small intestine, histologically diagnosed as leiomyoma, presented in Surgery Emergency Ward with intestinal obstruction, treated conservatively with no improvement and hence subjected to emergency exploratory laparotomy which revealed intussusception and leading cause of which was a benign leiomyoma. The literature is revised emphasizing issues of pathophysiology, specific characteristics and the treatment of this tumour.

Keywords: Benign tumour, intestinal obstruction, intussuception, jejunum, leiomyoma.

Case Report

A 55-year-old male was admitted to the emergency surgery ward of Rajindra hospital, Patiala with acute abdominal pain and distension. The pain was diffuse, recurrent, dull in nature associated with anorexia, vomiting and constipation for the last five days. On examination, the abdomen was distended with generalized tenderness. On auscultation, the bowel sound was absent. The ultrasound examination revealed fluid collection in the pelvis. The patient was managed conservatively for two days, however he continued to have vomiting and increasing abdominal pain. There was no improvement in the symptoms, so he was subjected to an emergency operation. Exploratory laparotomy revealed the presence of a jejuno-jejunal intussusception. Following manual reduction, there was a tumor palpable at mid-jejunum (as the lead-point causing intussusception) with healthy small intestine except for mild congestion of the reduced portion. The tumour was brownish in color, firm in consistency, measuring 1.5cm in diameter, near the mesenteric border of the bowel and occupying almost the whole intestinal lumen (Fig.1). Segmental resection of the small intestine with tumour free margin was performed with end-to-end anastomosis.
was done. Surgical exploration of the abdominal cavity failed to reveal any other abnormality.

Histology revealed an intestinal leiomyoma with no malignant evidence (Fig. 2). The postoperative course of the patient was uneventful and the patient was discharged on the 15th postoperative day. (Because our patients prefer to stay till the sutures are removed.) Patient is doing well after the discharge and is on regular follow-up.

Discussion

Tumours of the small intestine are rare. Even though the small bowel accounts for 80% of the length and 90% of the mucosal surface of the gastrointestinal tract, only 3% to 6% of gastrointestinal tumors and 1% of gastrointestinal malignancies arise from the small bowel. Most small bowel tumors are incidental findings at operation or autopsy. Smooth muscle tumors of the gastrointestinal tract can be classified as leiomyomas, leiomyosarcomas and high grade leiomyosarcomas, depending on the cytological atypia and mitotic rate.

It is usually diagnosed in the fifth decade of life, although it may occur at any age. There is no sex predilection. Though most common in jejuno-ileal, there has been a disproportionately high incidence of smooth muscle neoplasm in Meckel’s diverticula, followed by the duodenum, if the unit area is considered. The distribution of these tumors in the alimentary tract, in the study from Taiwan in 1995,(8) in decreasing order of frequency, were found in the stomach (40%), jejunum (20%), ileum and rectum (14.3% each), duodenum (8.57%) and esophagus (2.86%).
highly vascular and ulcerate, Gastrointestinal (GI) bleeding is the most frequent presentation (75%), particularly in the duodenum. Whereas, only 25% present with obstructive symptoms like intra-luminal growth and compression or intussusception. The various clinical presentations are gastrointestinal bleeding (43.8%), abdominal mass (37.5%), abdominal pain (21.3%) and obstruction (16.4%). No symptom or sign were evident in 8.8% of the cases studied. (8)

In a recent study of 1074 patients with leiomyomas, intussusception was a common finding, with ileal tumors occurring in about 40% of the patients (10) but jejunal leiomyomas causing intussusception as in the present case is a rare entity which has not been reported in literature.

Pre-operative diagnosis of jejunal leiomyomas is difficult, partly owing to their rare occurrence and partly to the lack of any pathognomonic signs. The treatment of jejunal leiomyoma is segmental resection with clear margins. Leiomyomas are difficult to differentiate from leiomyosarcomas, even on pathological examination. Lymph node resection is not routinely required because even leiomyosarcoma does not spread via lymphatics.

Conclusion

Leiomyomas of the gastrointestinal tract is infrequent and usually found incidentally at autopsy. If symptomatic, may present with GI bleeding. Intussusception was a common finding, with ileal leiomyomas but jejunal leiomyomas causing intussusception is not reported in literature. Preoperative diagnosis is difficult to make owing to the absence of specific clinical symptoms and difficulties in radiologic evaluation of small bowel. Furthermore, the rarity of the condition does not allow any one surgeon or center to gain sufficient expertise. Hence, this rare diagnosis of jejunal leiomyoma should be kept in mind while dealing with small intestinal obstruction.
